

InstallPros

Gustavo Polin

Overview

InstallPros Technician App, an internal product concept for streamlining Starlink installations across the U.S.

A clean, trusted experience that would help technicians manage jobs, payments, and customer satisfaction in one platform.

The Problem

Technicians receive job details through emails and chat messages, which leads to delays, missed confirmations, and inconsistent documentation. The process is manual, fragmented, and difficult to manage at scale, especially across multiple regions and contractors. The goal of this concept: a simple, reliable tool for technicians that makes their daily work smoother while improving operational visibility for InstallPros.

The Challenge

Technician profiles range from highly tech-savvy installers to those new to digital tools. The app has to work offline, integrate ID verification, photo uploads, and payments in one smooth experience, all while feeling friendly and confidence-inspiring.

User Personas

Technicians operate in unpredictable environments, from remote rural areas to fast-paced urban installations. Understanding their workflows, frustrations, and operational needs helped shape a more reliable and intuitive field experience.

Ethan Cole
Independent Contractor

Age 35
Experience Level 3-5 years

I just want to see all my jobs in one place, finish, upload proof, and get paid, simple as that.

Goals

- ✓ Steady, predictable job flow.
- ✓ Fast payment after each job.
- ✓ A reliable system for job details and verification.

Pain Points

- Losing job info through chat or email.
- Unclear payment timelines.
- Manual paperwork and delayed confirmations.

Needs

- Centralized job management.
- Instant payment tracking.
- Easy photo & signature collection for proof.
- Transparent job acceptance flow.

Marcus Hill
In-House or Partnered Technician

Age 38
Experience Level 5-7 years

Some days I'm in the mountains, I need the app to work even if my signal drops.

Goals

- ✓ Clear onboarding and job instructions.
- ✓ Guidance through the installation process.
- ✓ Confidence completing all verification and customer sign-off.

Pain Points

- Uncertainty about which steps are mandatory.
- Fear of making errors that delay payment.
- Unfamiliar with technical or compliance requirements.

Needs

- Guided onboarding.
- Step-by-step job process with offline support.
- Tutorials or example photos for reference.
- Clear feedback at each stage.

Access & Security

Access is protected by biometric and 2FA verification, so a technician can get into the app in seconds on site without leaving the account open on a shared or lost phone.

Identity Verification

New technicians verify their identity before the account activates. The gate is there because the network's integrity has to start at the door, not at the install, a stranger is about to represent the brand on someone's roof.

Onboarding & Personalization

The onboarding flow was designed to reduce setup friction and help technicians quickly configure availability, schedules, and upcoming installations.

Job Management

A centralized Jobs hub gives technicians full visibility into upcoming installations, active assignments, and real-time job updates, reducing dependency on fragmented communication channels.

Who sees the address, and when?

The decision: the exact address appears only after the technician accepts the job.

Before accepting, a technician sees the service, the date, the pay and the distance. That is enough to judge whether the job is worth taking. The street address stays hidden until they commit. Customers are letting a stranger into their home, and an open list of addresses is a liability the business can't carry.

Trade-off accepted

The technician commits before knowing exactly where they are going, which is a real cost for someone planning a route around their own day. Distance and area are shown up front so that decision stays informed without exposing the customer.

Installation Workflow

Each job follows a guided step-by-step process, from photo verification and add-ons to secure payment collection.

What happens when the signal drops?

The decision: every step of the installation works offline first.

The customer is buying satellite internet because coverage there is poor, so the product has to assume no signal at the exact moment of work. Progress, photo evidence and completion are captured locally and reconciled when a connection returns. The technician gets a confirmation, not a spinner.

Trade-off accepted

Local state and conflict resolution cost far more engineering than a connected-only app, and dispatch sees some data late. A tool that fails where the job actually happens is not a tool.

Designing for the Bad Day

Most of a field tool's value shows up when something fails. Nothing scheduled, no signal on a roof, a document the system can't read. Each one needed an answer that keeps the technician moving instead of calling dispatch.

Payment Flow

One of the biggest concerns for technicians was payment visibility and payout reliability.

The payment flow was designed to provide clear earnings tracking, transparent payout status, and frictionless integration with Stripe and PayPal.

Who can change the price on site?

The decision: the technician can add costs mid-job, inside the workflow.

Installs meet reality: extra cable, a second trip, custom mounting. Those costs used to become a phone call and an invoice argument days later. Additional costs are itemised by type during the job, so the change is recorded where it happens, with the customer still there.

Trade-off accepted

Letting a contractor change the price opens an obvious trust surface in both directions. Constraining it to named categories instead of a free amount keeps the change legible to the customer and auditable for the business.

Completion & Feedback

Completion closes with a signature and a prompt for customer feedback, captured on site while the technician is still there rather than chased down afterwards.

Collect Feedback

Ask the customer to scan the QR code to leave a review.

Mark Job as Completed

What closes a job?

The decision: a job is not complete until the work is photographed, item by item.

Completion walks a fixed checklist (satellite, mount, cable run, entrances, router location, speed check, obstruction check), and each one needs an image. Evidence is captured while the technician is still on site, not reconstructed from memory when a customer disputes the install weeks later.

Trade-off accepted

Deliberate friction at the end of a long day, when the technician most wants to leave. It is the cheapest insurance the business has, and it is what makes paying out immediately safe.

Operational Context

InstallPros has completed over 9,000 installations and processed more than \$7M in revenue across its technician network. That is the operation this concept was designed for, not a result it produced.

This concept explored how mobile-first workflows could help streamline operations, reduce friction, and improve technician efficiency in the field. It was never built, so nothing here is measured. What I'd instrument first is job completion time, callback rate, and time to first payout.

Each installation represents a household, school, or business gaining access to reliable high-speed internet, bridging the digital divide one connection at a time.

Final Reflection

This exploration helped define how mobile-first workflows could improve communication, reduce cognitive load, and create a more scalable technician experience for InstallPros.

It was scoped for a small engineering team from the first screen, because a concept is only worth proposing if someone can actually build it. That constraint shaped the pattern system more than any visual decision did.
